A Complexity Primer for Systems Engineers

Revision 1 2021

WHITE PAPER

COPYRIGHT INFORMATION

This INCOSE Technical Product was prepared by the International Council on Systems Engineering (INCOSE). It is approved by the INCOSE Technical Operations Leadership for release as an INCOSE Technical Product.

Copyright © 2016 & 2021 by INCOSE, subject to the following restrictions:

Author Use. Authors have full rights to use their contributions in a totally unfettered way with credit to the INCOSE Technical source. Abstraction is permitted with credit to the source.

INCOSE Use. Permission to reproduce and use this document or parts thereof by members of INCOSE and to prepare derivative works from this document for INCOSE use is granted, with attribution to INCOSE and the original author(s) where practical, provided this copyright notice is included with all reproductions and derivative works.

External Use. This document may not be shared or distributed to any non-INCOSE third party. Requests for permission to reproduce this document in whole or part, or to prepare derivative works of this document for external and commercial use should be addressed to the *INCOSE Central Office, 7670 Opportunity Rd., Suite 220, San Diego, CA 92111-2222*.

Electronic Version Use. Any electronic version of this document is to be used for personal, professional use only and is not to be placed on a non-INCOSE sponsored server for general use. Any additional use of these materials must have written approval from INCOSE Central.

ACKNOWLEDGEMENTS

This Primer is the product of an extended effort of the INCOSE Complex Systems Working Group. The document was written via a series of bi-weekly teleconferences over approximately 5 months, which included frequent review by new teleconference participants. The Working Group is grateful to these contributors and participants, who should collectively be considered the authors of this Primer: Sarah Sheard, Stephen Cook, Eric Honour, Duane Hybertson, Joseph Krupa, Jimmie McEver, Dorothy McKinney, Paul Ondrus, Alex Ryan, Robert Scheurer, Janet Singer, Joshua Sparber, and Brian White. Drafts were offered for review to the full working group, and to individuals expressing interest at subsequent INCOSE workshops and symposia.

The Working Group is also grateful to others outside of the working group for their contributions to refining the current draft. We would like to thank the team from Lockheed Martin, led by Mr. Garry Roedler, who provided extensive comments, including candidate topics for exposition in future working group products. We have also had the opportunity to provide an overview of the key concepts in this primer to a number of audiences, including the INCOSE Systems Science Working Group and the INCOSE Enchantment Chapter, each of whom provided useful feedback on the importance of these ideas and how to effectively present them, which will have a positive impact on future revisions.

We wish to thank Dr. Scott Jackson for his review and suggestions for improvements to the original material, which will be reflected in the next version of the document.

Finally, the Working Group is indebted to Dr. Sarah Sheard, who chaired the working group during the inception of the Primer and most of its development for her leadership and the many contributions she has made to the practice of systems engineering in the context of complexity.

Dean Beale, Dorothy McKinney, and Michael Watson developed this first Revision of the Primer as an addition to the original content. The revision incorporates advancements recognized by the Working Group in the definition of complex systems and the identification of complex systems characteristics.

I. INTRODUCTION

Complexity is nothing new to systems engineering practitioners and managers. The discipline of systems engineering evolved to improve our ability to deal with scale, interdependency, and complexity in systems development. Few systems engineering practitioners would doubt that complexity is increasing every year. The rate of change, the increasing interdependence and adaptability of systems, and the increasing ambitions of our clients ensure that complexity keeps expanding to the limits of our capacity to cope with it.

Complex systems science provides a strong foundation for understanding, coping with, and even exploiting complexity. There is a large and rapidly expanding literature on networks, complexity, and complex adaptive systems that can guide systems engineering practice. However, busy systems engineering practitioners rarely have the time to keep up with this literature, which is diffused across the many interdisciplinary applications of complex systems science. This paper is written for systems engineering practitioners and program/project managers who suspect they may encounter complexity-related challenges. This paper applies key concepts from complex systems science to systems engineering to suggest new methods that can handle complexity rather than assuming it away. It is not a complete or even extensive treatment, but is intended as an introduction to the subject for systems engineering practitioners as they encounter and work with complexity-related phenomena.

Section II of this paper defines complexity and describes how we can identify complexity in an environment, a problem space, or a solution space. We also address the extent, types of complexity that a system or situation may exhibit, and the characteristics of complex systems; so that systems engineering practitioners can seek approaches that can better address that kind of complexity.

Section III then discusses how engineering practitioners address the problem of complexity through two approaches. The first approach highlights the need to think differently about the environment, the problem and the solution. The second approach involves the selection and implementation of specific tools and techniques.

II. WHAT IS COMPLEXITY?

In ordinary language, we often call something complex when we can't fully comprehend its structure or behavior: it is uncertain, unpredictable, complicated, or just plain difficult. Sillitto (2009) described the inability of a human mind to grasp the whole of a complex problem and predict the outcome as subjective complexity. John Warfield's (2006) "frustration" in the mind of the system's builders and users also fits into this bucket. While there are ways to reduce this complexity and improve the fit of technical systems into the complex environment, they are not the focus of this primer.

Sillitto's Objective Complexity describes technical or system characteristics that lead to the subjective complexity or difficulty. As systems engineering practitioners, we have the ability to modify these characteristics; they are also the ones most frequently addressed by complex systems science. The standard systems engineering process breaks down a problem into parts, recursively, until the parts are simple enough that we understand them and can design solutions; we then re-assemble the parts to form the whole solution. The approach works well for systems whose parts interact in fixed ways (also known as "complicated" systems – an example might be a car), even when there are many interacting parts and the systems may appear to have unpredictable behavior.

Other systems, however, present significant problems when analyzed in piecewise fashion. Systems such as transportation networks have autonomous parts whose interactions lead to emergent self-organized patterns of behavior. In these systems, defined here as "complex" systems, the emergent properties that we really care about are not understandable from the perspective of the parts in isolation. It is especially for these systems that we are providing guidance to additional tools and techniques created in complex systems sciences and recommend their use in systems engineering of complex systems.

Complex systems are not complex in all of their characteristics as defined in Table 1. Complicated systems can have complex characteristics and not all characteristics of a complex system may be complex. Even simple systems can have complex effects on social systems in application. Thus, complexity is not a simple yes or no attribute. Complexity is based on multiple characteristics not all of which are likely to be found in a single system. Even a complex adaptive system only shows complexity in some of the characteristics of the system indicating the other characteristics may have more of an effect on a systems' complexity than adaptability.

The definition of complex, complicated, and simple systems can be delineated using the Latin etymology of the words. This leads to specific and useful definitions for these different views of systems which bridges subjective and objective complexity, since comprehension can depend on the observer.

A simple system has elements, the relationship between the states of which, once observed, are readily comprehended.

A complicated system has elements, the relationship between the states of which can be unfolded and comprehended, leading to sufficient certainty between cause and effect.

A complex system has elements, the relationship between the states of which are weaved together so that they are not fully comprehended, leading to insufficient certainty between cause and effect.

As seen by this definition, traditional systems engineering approaches, which assume some form of order and deterministic behavior so the relationship between cause and effect is understood, do not handle complex systems engineering well.

A. CHARACTERISTICS OF COMPLEXITY

The difference between a simple or complicated system and a complex one has to do with the interactions of the element states. States in one element typically affect states in other elements—or states in the elements may affect external environment—or self-organization may change the states in many elements simultaneously. For example, a complex adaptive system is a complex system capable of changing itself over time. The result is that rigorous application of traditional systems engineering methods often leads to misunderstanding rather than certainty. It is often not feasible to study a complex system by partition and reduction, because behaviors only exist when the system is entire. It is worth noting that complexity can and does occur even with few elements in a system.

Complexity is a characteristic of more than just a technical system being developed. It is often created by the interaction of people, organizations, and the environment that are part of the complex system surrounding the technical system. Complexity results from the diversity, connectivity, interactivity, and adaptivity of a system and its environment. Constant change makes it difficult to define stable goals for a project or system. Technical systems that worked well in the past to solve an environmental problem become obsolete quickly. Intricate networks of evolving cause-effect relationships lead to subtle bugs and surprising dynamics. Unintended consequences can overwhelm or even negate the intended consequences of actions.

Complex systems tend to exhibit variety in their characteristics rather than uniform repetition. There are 14 distinguishing characteristics of complexity identified in Table 1 along with their definitions. Systems may exhibit one or more of these complexity characteristics. People understand systems using mental models. When people do not have a mental model which supports understanding of a complicated system, that system will probably appear complex to them. When systems are complex, their structures cannot be described at a single level or with a single view; multi-scale descriptions are needed to understand complex systems. Their emergent behavior, derived from the relationships among their elements and with the environment, via internal and external feedback loops, gives rise to observed patterns that may not be understood or predicted. Describing the behavior of a system as a response function may require an unobtainable amount of information. It is often impossible to predict future configurations, structures, or behaviors of a complex system, given finite resources.

A complex system may have multiple stable states (meaning each state is actually meta-stable), transient states, or even no lasting stable states, exhibiting continuous evolution. Perturbations in the system may result in recovery to the former state but may also lead to transitions to another state and consequent radical changes of properties. In addition, details seen at the fine scales can influence large-scale behavior. Dynamics of different parts and patterns cannot be reproduced using simple averages.

Complex systems are perpetually generating novelty, many key variables are opaque, boundaries are indeterminate, and weak ties can have a disproportional effect on system behavior. Duality is common: tension between large and small, distributed and central, agile and planned calls for perpetual seeking of balance. In short, complex systems are different.

Although complexity can present challenges, complexity is often inherent and may even be a necessary or desirable attribute of a solution system. Systems that have been engineered to rule out any but deterministic behaviors are necessarily limited by the prescribed behaviors, and do not extend well into unplanned environments. In contrast, complex systems can be engineered to have sufficient adaptability to operate well in a changing environment, responding to change in appropriate and effective ways. A complex system provides a welcome kind of variety that can help provide control of different dimensions and enables the system to adapt to environmental change. Providing new capabilities or graceful degradation, a complex system can adapt by re-organizing its structure, responses, or patterns of parts.

Table 1. Characteristics of complexity

Characteristic	Definition
Diversity	The structural, behavior, and system state varieties that characterize a system and/or its environments. Complex systems tend to exhibit significant diversity.
Connectivity	The connection of the system between its functions and the environment. This connectivity is characterized by the number of nodes, diversity of node types, number of links, and diversity in link characteristics. Complex systems have multiple layers of connections within the system structure. Discontinuities (breaks in a pattern of connectivity at one or more layers) are often indications of complex system connectivity. Simple and some complicated systems may be characterized by simpler structures such as hierarchies.
Interactivity	The behavior stimulus and response between different parts of a system and the system with its environment. Complex systems have many diverse sources of stimulus and diverse types of responses. The correlation between stimulus and response can be both direct and indirect (perhaps separated by many layers of system connectivity). The types of stimuli and responses vary greatly. The levels of stimuli and responses can range from very subtle to very pronounced. The timeframe for system responses can vary hugely.
Adaptability	Complex systems proactively and/or reactively change function, relationships, and behavior to balance changes in environment and application to achieve system goals.
Multiscale	In complex systems, behavior, relationships, and structure exist on many scales, are ambiguously coupled across multiple scales, and are not reducible to only one level.

Characteristic	Definition
Multi-Perspective	Multiple perspectives, some of which are orthogonal, are required to comprehend a complex system.
Behavior	Complex system behavior cannot be described fully as a response system. Complex system behavior includes nonlinearities. Optimizing system behavior cannot often be done focusing on properties solely within the system.
Dynamics	Complex systems may have equilibrium states or may have no equilibrium state. Complex system dynamics have multiple scales or loops. Complex systems can stay within the dynamical system or generate new system states or state transitions due to internal system changes, external environment changes, or both. Correlation of changes in complex systems to events or conditions in the system dynamics may be ambiguous.
Representation	Representations of complex systems can be difficult to properly construct with any depth. It is often impossible to predict future configurations, structures, or behaviors of a complex system, given finite resources. Causal & influence networks create a challenge in developing 'requisite' conceptual models within these time and information resource constraints.
Evolution	Changes over time in complex system states and structures (physical and behavioral) can result from various causes. Complex system states and structures are likely to change as a result of interactions within the complex system, with the environment, or in application. A complex system can have disequilibrium (for example, non-steady) states and continue to function. Complex system states and structures can change in an unplanned manner and can be difficult to discern as they occur. The changes in the states and structure of a complex system are a natural function of (is often present in) the complex system dynamics. Changes can occur without centralized control, due to localized responses to external and/or internal influences.
System Emergence (General)	Features/behavior associated with the holistic system that are more than aggregations of component properties.
Unexpected Emergence (Complex)	Emergent properties of the holistic system that are unexpected (whether predictable or unpredictable) in the system functionality/response. Unpredictable given finite resources. Behavior not describable as a response system.
Disproportionate Effects	Details seen at the fine scales can influence large scale behavior. Small scale modifications can result in radical changes of behavior. Scale can be in terms of magnitude of effect or aggregate amount of change. Weak ties can have disproportionate effects.
Indeterminate Boundaries	Complex system boundaries are intricately woven with their environment and other interacting systems. Their boundaries can be non-deterministic. The boundary cannot be distinguished based solely on processes inside the system.
Contextual Influences	All systems reside in natural and social environments and relate to these. In the relationship between the system and the natural and social environments there can be complexity. This complex interaction depends on the social application of the system. Social systems often strive to achieve multiple, sometimes incompatible, objectives with the application of the same system.

B. IDENTIFYING THE RIGHT LEVEL OF COMPLEXITY

Science and engineering help humans to make successful systems because they provide ways to understand, predict, and control technology, in order to create desirable effects on the world. All science involves abstraction of the complexity of the world into models that use simplifying assumptions. These allows us to generalize from one complex situation to another. The best engineering methods take advantage of the simplicity of the models to predict behavior and achieve control while ensuring that the models adequately represent the system being modelled.

As a system's diversity, connectivity, interactivity, or adaptivity increases, the risk associated with using simpler methods and simplifying assumptions also increases, and more advanced techniques may be needed. Tools and techniques apply differently to systems on a spectrum of increasing complexity. At the less complex end, the waterfall model for top-down sequential design applies well. At the more complex end, tools such as agent-based models for model-based systems engineering can be used to understand and address complex, dynamic system design challenges. Techniques at the lower end of the spectrum tend to be easier to learn, and simpler and faster to apply, because they make simplifying assumptions that ignore some of the complexity. The practitioner must apply judgement to utilize a mixture of tools along this spectrum that satisfies Einstein's razor: make things as simple as possible, but not simpler.

It is rarely possible to fully assess in advance what complexity within a project must be addressed and what can be assumed away. Because complex systems perpetually generate novelty, systems engineering practitioners will often have to adapt their approach to unfolding conditions and use flexible tools. Practitioners should also recognize that system complexity provides a welcome kind of variety that can help facilitate control of different dimensions and enables the system to adapt to environmental change.

III. SOLUTIONS FOR COMPLEXITY

Throughout its history, systems engineering has been the primary method for engineering in the face of complexity. As the complexity of systems and their contexts has grown, systems engineering methods and tools have increasingly fallen short of what is needed in the face of this reality. A common approach has been to seek clever ways to simplify, or reduce, the subjective complexity so that the problem and the system are understandable. Scientific advances have, in fact, often come from elegant simplifications that model the important variables or forces that dominate behavior. However, this is not always possible – complexity often cannot be simplified away without losing the essence of the problem or possible solutions. Further, this simplification leads to an inability on the part of the solution to be able to engage with the complexity that remains despite our preference to assume it away.

Ross Ashby's Law of Requisite Variety shows that a system controller must have at least as many degrees of control as the degrees of freedom in the environment to be controlled. If a system operates within an environment of human processes, as in today's air traffic control, then the system solution must have sufficient complexity to do so. In such a system, it is difficult and even dangerous to ignore the complexity.

Therefore, it behooves systems engineering practitioners to acknowledge, understand and learn to work better with complexity. A first step is to identify the kinds of complexity in a system and its environment (Section II). This involves identifying which aspects of the system and its environment can be controlled by the system engineer, which ones can be influenced (but not fully controlled), and which environmental influences can be responded to but not controlled. A second step is to create appropriate new ways to think about complexity to guide the approaches selected (Section IIIA). A third step is to evolve and publicize methods to deal with different types of complexity in different situations (Section IIIB).

Working with complexity will never be a trivial task that can be reduced to following a checklist. The complex, adaptive neural network of our human brains will always be needed to supplement documented lessons of any sort. A long-term goal of the INCOSE Complex Systems Working Group is to facilitate the systems engineering community's collective learning with non-trivial lessons, heuristics, and shared stories, all of which are outside the scope of this Primer. We acknowledge that the world is complex, and that our orderly, implications of complexity – in our systems, in their ecosystems (both technical and socio-political), and in the interplay between the two – in order to be successful.

A. COMPLEXITY THINKING: GUIDING PRINCIPLES

Complex systems engineering requires both a shift in thinking and an expanded set of tools and techniques. In this section, we summarize the shift in thinking needed to acknowledge and embrace complexity within systems engineering. Several principles are provided below that encourage systems engineering practitioners to think differently about how to engage with complexity.

1. **Think like a gardener, not a watchmaker.** Consider the complexity of the environment and think about the solution as a living entity within a changing environment as opposed to an intricate, static machine.
2. **Combine courage with humility.** It takes courage to acknowledge complexity, relinquish control, encourage variety, and explore unmapped territory. It takes humility to accept irreducible uncertainty, to be skeptical of existing knowledge, and to be open to learning from failure. A combination of courage and humility enables the complex systems engineer to risk genuine innovation and learn fast from iterative prototyping of solutions in context.
3. **Take an adaptive stance.** Systems engineering practitioners should mimic how living systems cope with complexity by identifying and creating variation, selecting the best versions, and amplify the fit of the selected versions. This means, for example, to think “influence” and “intervention” rather than “control” and “design.” Designing or evolving a complex system requires recognition that the designer may not ever be able to control or even understand the system completely.
4. **Use free order.** In architecting and designing solutions, build in “order for free” using self-organization, presuming it has been modeled and can be limited to desired effects. This in particular applies when the system being designed must be resilient.
5. **Identify and use patterns.** Patterns are exhibited by complex systems, they can be observed and understood, and are a key concept in the engineering of complex systems. Patterns are the primary means of dealing specifically with emergence and side effects—that is, a means for inducing desired emergence and side effects, and a means for avoiding undesired emergence and side effects.
6. **Zoom in and zoom out.** Because complex systems cannot be understood at a single scale of analysis, systems engineering practitioners must develop the habit of looking at their project at many different scales, by iteratively zooming in and zooming out. Can problems be solved more elegantly by addressing them at a higher or lower hierarchical level? The complex systems engineer must be especially open to solutions that arise from the bottom-up through self-organization, rather than only seeking to impose order from the top-down.

7. **See through new eyes.** A complex situation often looks very different from the perspectives of the variety of stakeholders. By empathizing with these multiple perspectives, a systems engineer can sometimes find creative ways to solve several problems at once.
8. **Collaborate.** Collaboration includes information sharing, active listening, establishment of trust to enable candid dialogue, and making decisions transparent. A collaborative mindset can lead to deeper stakeholder engagement practices that may include crowdfunding and crowdsourcing to enable co-creation and co-evolutionary systems design.
9. **Achieve balance.** Optimization is often counterproductive within a complex system. Either the whole is sub-optimized when a part is optimized, or an optimized whole becomes rigid, unable to flex with changing conditions. Instead of optimizing, complex systems engineers should seek balance among competing tensions within the project. Systems engineering practitioners can leverage integrative thinking to generate improved solutions and avoid binary either/or tradeoffs. The goal is a system that would continue to meet the need even if a number of current conditions change.
10. **Learn from problems.** In a changing context, with an evolving system, where elements are densely interconnected, problems and opportunities will continually emerge. Moreover, they will emerge in surprising ways, due to phase transitions, cascading failures, fat-tailed distributions, and “black swan” (Taleb, 2007) events. A traditional approach to risk management and mitigation should be augmented by a complexity mindset that balances risk management with exploiting opportunity and expects and learns from error.
11. **Meta-cognition.** Meta-cognition, or reflecting on how one reflects, helps to identify bias, make useful patterns of thinking more frequent, and improve understanding of a complex situation.
12. **Focus on desired regions of outcome space rather than specifying detailed outcomes.** Instead of zeroing in on an exact solution, focus on what range of solutions will have the desired effects, and design to avoid forbidden ranges.
13. **Understand what motivates autonomous agents.** Changing rewards will shape collective behavior. Implement incentives that will move the system toward a more desired state.
14. **Maintain adaptive feedback loops.** Adaptive systems correct for output variation via a feedback mechanism. Over time, feedback loops can either hit the limit of their control space, or may be removed in the interest of maintaining stability. To maintain robustness, periodically revisit feedback and ensure adaptation can still occur.
15. **Integrate problems.** Focus on the relationships among problems rather than addressing each problem separately. This allows fewer solutions that take care of multiple problems in an integrative fashion.

B. SPECIFIC METHODS

The principles and approaches described above are important points of departure for systems engineering practitioners facing complexity in their systems engineering activities. It is also useful to describe how these concepts apply to particular aspects of the systems engineering practitioner's work – aspects that are fundamental regardless of the nature of the system being developed or the problem being addressed. Systems engineering practitioners' toolkits should include a wide range of methods and processes to address environmental and system complexity in appropriate and useful ways.

A key first step is one of diagnosis – the systems engineering practitioner must identify the kind and extent of complexity that bears on the problem set. As we have seen, complexity can exist in the problem being addressed, in its environment or context, or in the system under consideration for providing a solution to the problem. Management of complexity may also be exacerbated by external pace of change or time constraints. The diagnoses made will allow the systems engineering practitioner to tailor his/her approaches to key aspects of the systems engineering process: requirements elicitation, trade studies, the selection of a development process life cycle, solution architecting, system decomposition and subsystem integration, test and evaluation activities, and others.

In addition, the diagnosis will allow the systems engineering practitioner to consider whether there may be mechanisms for shifting complexity to a more desirable region of the problem space. There may be choices available or investments that can be made to allow the decoupling of aspects of the system or of the system to its environment. Likewise, there may also be options for shaping the feedbacks within and across problem-environment-solution elements, allowing the complexity of the situation to be harnessed via the leveraging of beneficial adaptation and self-organization.

The table in the following page shows examples of the kinds of choices that can improve the success of engineering complex systems when complexity of different types and from different sources exists. These lists are by no means exhaustive; indeed, astute readers will note that some entries in the tables below are blank. These tables are intended to convey the types of approaches and departures from traditional systems engineering methods that may be required when dealing with complexity in problem, solution, and environment contexts. The authors expect that these tables will be augmented and evolved in future updates to this primer.

These approaches are offered to help systems engineering practitioners ensure that their processes are appropriate for dealing with the dynamics, uncertainty and behaviors that can arise when significant complexity exists in the problem, the solution, or the environment. Experience suggests that when systems engineering activities do not account for these factors when they exist, projects fail and problems go unaddressed. Our

goal in this primer is to provide systems engineering practitioners with techniques for better recognizing complexity and its consequences as it pertains to their activities, and for expanding the envelope of the degree and types of complexity that can be dealt with. Without doubt, there is additional work to do to expand our understanding of these phenomena – and to provide practical tools to allow the systems engineering community to leverage and better apply emerging insights. The concepts and approaches in this section, however, should provide a useful starting point.

The candidate approaches shown in Table 3 have proven to be effective, but do not represent a systematic or comprehensive set of approaches for dealing fully with the situations noted in the left column. However, noticing when you have any of the situations listed in the left column, and taking specific steps to deal with them, rather than relying on traditional systems engineering practices, is much more likely to result in a successful outcome.

Table 2. Systems engineering focus for different views of systems

Type of System	Key Systems Engineering Focus
Simple	Concentrate on choices of elements to build the system and use traditional systems engineering approaches described in the INCOSE Systems Engineering Handbook.
Complicated	Seek information to more fully understand the relationship between system elements and emergent properties of the system and use traditional systems engineering approaches described in the INCOSE Systems Engineering Handbook.
Complex	Identify the sources of complexity and use different approaches as described in Table 3 below for that class of complexity rather than traditional systems engineering to address these areas.
Complex Adaptive	Concentrate on understanding possible emergent characteristics; some approaches described in Table 3 below may be helpful. New approaches for systems engineering complex adaptive systems are still being discovered. These almost certainly will involve development of established complex systems approaches and a move towards continual evolution as evidenced to Agile systems engineering.

Table 3. Candidate approaches to address complexity in problem context or environment

	Requirements Elicitation and Derivation	Trade Studies	Solution Architecture and Design	Development Process
Complexity in the Environment General	<p>Use multiple methods for requirements elicitation.</p> <p>Elicit requirements from multiple perspectives and at multiple levels of aggregation.</p> <p>Emphasize capture of system objectives and desired outcomes rather than thousands of detailed requirements.</p>	<p>Emphasize robustness over local efficiency and performance.</p>	<p>Include both positive and negative feedback mechanisms to provide mechanisms to compensate for the effects of higher-than-linear positive feedback and runaway system behavior.</p>	<p>Employ soft systems methodologies to surface the nature of the problem space, its internal structure and information flows, and produce simple representations, for example 'rich pictures' to communicate these.</p>
Intricate and Evolving/Self-Organizing Interactions with the Environment	<p>Include requirements for the system to provide adaptive local control, rather than strong, deterministic control.</p>	<p>Trade end-to-end system performance and behavior against problem space complexity. Think hierarchy rather than flat networks.</p>	<p>Early implementation (or at least prototyping) of external interfaces.</p>	<p>Early deployment of system functionality with feedback to developers.</p>
Environment Susceptible to "Black Swan" Events (Unlikely, Unpredictable, High-Consequence Events) and/or Recursive Complexity	<p>Use power laws rather than Gaussian distributions to characterize phenomena in requirements and self-off criteria.</p> <p>Focus requirements elicitation on resiliency, robustness and adaptiveness vice optimizing to particular assumptions.</p>	<p>Make resilience a key trade-space attribute and use trades to identify aspects of the problem space that will drive the system architecture.</p>	<p>Design for resilience to "beyond-design-envelope" events to provide robustness and timely recovery to a minimally functional state.</p>	<p>Resilience analysis. Enterprise development: study how enterprises or societies survive catastrophes.</p>
Complexity in the Problem/Mission	<p>Emphasize identification of constraints as well as requirements.</p> <p>Capture scenarios and mission threads in preference to large numbers of requirements.</p>	<p>Use scalability and agility as criteria in appropriate trade Studies.</p>	<p>Use solution elements which are adaptable and/or reconfigurable.</p> <p>Design to achieve scenarios rather than detailed requirements.</p> <p>Satisfice at the system level rather than satisfy detailed requirements.</p>	<p>Use Agile, evolutionary systems engineering processes instead of Waterfall systems engineering processes. Define multi-layer processes and their interface points.</p>
Complexity in Stakeholder Relationships	<p>Use multiple scales (or a Balanced Scorecard approach) instead of a single utility function to determine "goodness" or fitness for use.</p>	<p>Seek stakeholder buy-in to trade studies.</p>	<p>Use modeling and simulation to enable stakeholders to experience (rather than just be briefed about) interactions of solution elements and the environment.</p>	<p>Employing a multi-methodological approach, for example, soft systems methodologies plus systems engineering plus boundary critique, to identify stakeholders and achieve buy-in.</p>
Complexity in Interactions Between Different Mission Elements	<p>Capture scenarios and mission threads in preference to large numbers of detailed requirements.</p> <p>Develop understanding and means of controlling non-linearities, disruptive events.</p>	<p>Make minimizing interactions interdependences between complex systems elements a key trade-off attribute. Model with system dynamics.</p>	<p>Use exploratory modeling and simulation to assess ability of solution elements to address mission elements under wide range of conditions and assumptions. Use system dynamics to link economics and system changes.</p>	<p>Establish and maintain an interdependency database between constituent systems that is used for all major design decisions.</p>

Table 4. Candidate approaches to address system solution complexity

	Requirements Elicitation and Derivation	Trade Studies	Solution Architecture and Design	Development Process
Complexity in System Design & Development (General)	<p>Use multi-scale modeling (linking macro- and micro-level models), including exploratory analysis and agent-based modeling, and experimentation:</p> <ul style="list-style-type: none"> To generate insight into the implications of derived requirements. As the basis for trade studies and to inform trade-off decisions. 		Emphasize selection of robust and adaptive elements and structures over optimizing to meet current requirements.	Use SoSE methodologies to synchronize constituent systems; incentivize collaboration. Ensure prototyping and experimentation are used.
Emergent Properties or Behaviors in Solution System	<p>Maximize description of emergent properties in scenarios and mission definition.</p> <p>Elicit requirements from multiple perspectives and at multiple levels of aggregation; ensure requirements and constraints at all relevant levels are understood.</p> <p>Understand the real value of predictability at different levels; encourage the definition of requirements at higher “essential value” levels.</p>	Employ modeling and experimentation to ensure relevant effects of trades are explored at different levels of aggregation.	<p>Build in feedback mechanisms to enable the system and system elements to adapt to the environment and each other in effective ways.</p> <p>Acknowledge the limits to the value of decomposition-based methods; emergence is a collective phenomenon that requires aggregation – emergence will not be observed until the system is considered as a whole.</p>	<p>Conduct development activities always within context of the whole.</p> <p>Employ collaborative development processes so that information about design decisions is visible throughout the project.</p> <p>Prototyping and holistic testing are critical to explore and check for the manifestation of emergent behavior.</p>
Complexity in System Deployment & Operation	<p>Employ soft systems methodologies to surface the nature of the deployed solution, and its internal structure and information flows; produce simple representations, for example, ‘rich pictures’ to communicate these.</p> <p>Use problem definition methods from an evolutionary systems engineering or SoSE methodology.</p>	Trade criteria need to value cost and ease of training and logistical support over acquisition cost. Model system evolution with genetic algorithms.	Use self-organizing and self-repairing elements when possible. Model the cost of change, the benefits, and the balance.	<p>Employ soft systems methodologies to surface issues, engage stakeholders, identify approaches to improve the deployed system, and to achieve stakeholder buy-in to the solution.</p> <p>Use an evolutionary systems engineering or SoSE methodology. Identify utility and cost of using and modifying legacy systems.</p>
Complexity in System Evolution & Support	Focus on capabilities, not requirements.	Use resilience and robustness as criteria in trade studies.	Ensure that the most important system elements are composable (that is, capable of being re-configured adaptively with other elements in the future to satisfy emergent operational needs not previously envisioned) and have clear and accessible interfaces.	Emphasize understanding the problem, and at each stage of this iterative process, intervene to add an incremental capability and watch carefully over time to see whether there is improvement. If not, try something else.

Tools to Analyze, Diagnose, Model and Synthesize, as shown in Table 5 below, can be very helpful in dealing with complex systems. Cook developed an initial list of methods useful for addressing different aspects of complex systems, which has been augmented by Shalizi (2006). The tools in each column generally range from the simplest at the top to the most complex at the bottom. These methods provide a starting point for systems engineers seeking complexity-appropriate modeling approaches for systems engineering.

Table 5. Selected modeling methods for complex systems

ANALYZE	DIAGNOSE	MODEL	SYNTHESIZE
Data Mining	Algorithm Complexity	Uncertainty Modeling	Design Structure Matrix
Splines	Monte Carlo Methods	Virtual Immersive Modelling	Architectural Frameworks
Fuzzy Logic	Thermodynamic Depth	Functional/Behavioral Models	Simulated Annealing
Neural Networks	Fractal Dimension	Feedback Control Models	Artificial Immune System
Classification & Regressions Trees	Information Theory	Dissipative Systems	Particle Swarm Optimizations
Kernel Machines	Statistical Complexity	Game Theory	Genetic Algorithms
Nonlinear Time Series Analysis	Graph Theory	Cellular Automata	Multi-Agent Systems
Markov Chains	Functional Information	System Dynamics	Adaptive Networks
Power Law Statistics	Multi-Scale Complexity	Dynamical Systems	
Social Network Analysis		Network Models	
		Agent Based Models	
		Multi-Scale Models	

IV. SUMMARY

Although the many different meanings of complexity vary, from “confusion” to measurable characteristics of technical systems, it is most useful to systems engineering practitioners to identify the complex system characteristics to improve the development and operation of modern systems. This primer has attempted to describe complexity in such a usable and useful manner. Complexity can be an attribute of the technical system being developed but also of the problem space (including people and organizations), and the environment. Complexity is associated with size, diversity, dynamism and with emergence. It is a challenge to systems engineering practitioners not to over-simplify in pursuit of representations and capabilities that can be understood and controlled; the right level of complexity is key.

We have shown principles to guide the extension of systems engineering practices to handle ever-more-complex situations and systems. We have also catalogued a number of systems engineering approaches based on concepts from complex systems science. These are shown on matrices of types of complexity and types of systems engineering practice (which may occur across any specific life cycle). We also list modeling methods that may be of use and are under consideration for longer explanatory articles.
